** Post-Rewrite Code Review Questions

1. Are there any unused dependencies in the project?
2. How can we check for unused deps in an automated way? Pre-commit hooks? CI?
3. How does the syntax highlighting system work?
4. The custom nix highlighting seems complicated.
5. We are overriding default feature sets in rust crates in ways I don't understand.
6. I should implement a skill that converts a codebase to an .org and epub.
7. What is clap?
8. How can I quickly get to the docs for a crate in rust? Emacs search function? Can it complete?
9. Should org-roam-export default to the project dir and not a path in .cache? The export is data for the renderer, and is produced by the serializer. Both of those are in the project.
10. We convert webp to webp?
11. Why collect_image_paths and collect_image_paths_inner?
12. Seems main.rs is too busy. boilerplate, org parsing, images, custom syntax, debug mode, html parsing. How can we abstract and architect this better? Needs deep-research.
13. Dates need to handle [ ] brackets
14. I need c++ syntax highlighting too
15. What does AST even mean?

17. We have some legacy config files from before the rewrite hanging around in the project.
- storybook
- eslint
- npmrc
- prettier
- dependabot

18. I believe we have some out of date actions
19. What happens to secrets in forks?
20. The emacs exporter reads like a foreign lang to me
21. What does pagefind-dev-shim mean?
22. I'd like a "recently viewed" side menu on desktop. Unsure what this looks like on mobile
23. How big can my index + alias list get before things start to slow down? It seems like [slug] reads the whole file.
24. Can I write htmlg into org docs and expect it to render?
